

Chapter 1

Computer Applications

In recent years, my approach to composing and performing music has reached a point where the development of computer applications runs simultaneously with my aesthetic and creative research. From the very start of composition and conception until the performance and realization, the computer applications that are developed and the artistic output merge within the same creative process. Therefore, my artistic practice is deeply connected to computer programming and the use of computer applications. It is worth mentioning that the applications developed as part of this process are vital to the musical results of the compositions and encompass an important aspect of the compositional process. In addition, these applications were developed for an artistic purpose and understanding how they work might give an insight into my compositional output. Moreover, they do not serve a function beyond the realization of the idiosyncratic elements that constitute my creative process. That is to say, these applications do not represent a contribution to the scientific community in relationship to the technological developments of computer music but instead represent a set of tools and documentation that other artists, musicians and composers might find useful for their own practice.

In the previous chapter, I explained some of the potential that technology has brought to music and how even though technological advancements do not necessarily represent artistic developments, they do provide with new possibilities for artistic innovation. It is because of these possibilities that I have become recently interested in using digital technology to create music. I am particularly interested in using technology for...

In this chapter, I will explain in detail a number of important computer applications that were developed together with my compositional practice. These applications were written in the [SuperCollider](#)¹ programming language. I decided to use SuperCollider as a platform to develop these computer applications because it integrates a powerful audio synthesis server using state-of-the-art

¹James McCartney, SuperCollider, 1996. URL: <http://www.audiosynth.com/>

technology with the versatility and capabilities of an object-oriented-programming (OOP) language. I chose SuperCollider over other data flow programming applications like [Max/MSP](#) and [Pure Data](#) (Pd) because of its robust synthesis server and the advantages of abstraction of a high-level OOP language.² Another advantage I saw in using SuperCollider is the fact that it is an open source application, which means that the code in which it is written is available for free and can be modified. Most of the computer applications I developed and which will be discussed in this chapter are written as SuperCollider classes,³ but some of them are extensions of already existing classes or code that can be evaluated in real-time in the interpreter. The applications discussed in this chapter were used in various of the works submitted and constitute compositional strategies that reflect some aesthetic concerns that are recurrent in my work.

1.1 Spectral Tracking

In previous chapter, I briefly explained how spectralism and C. Barlow: *Synthrummentation* influenced my work.

Fast Fourier Transform (FFT)⁴

MIDI⁵

Spectrum analysis for dynamics, pitch and rhythm extraction.

1.1.1 PartialTracker

[PartialTracker](#) is a SuperCollider class for real-time partial extraction that diminishes the amount of FFT data by selecting the loudest bins and discarding the softer magnitudes with the purpose of having a limited amount of values to be returned as simple arrays for frequency and magnitude. It does so by taking an incoming audio signal, performing an FFT analysis and discarding spectral data in two ways: either by passing only the bins that are above a given magnitude threshold or by selecting a value that returns the strongest number of bins. For this purpose, I used the `PV_MagAbove` and

²See James McCartney, “Rethinking the Computer Language: SuperCollider”, in *Computer Music Journal*, volume 25, number 4, pp. 61-68, 2002, for a discussion about the differences between SuperCollider and Max/MSP, Pd and Csound.

³SuperCollider classes are descriptions of the structure and implementation of a set of objects that represent the instances of the class.

⁴See Curtis Roads, *The Computer Music Tutorial*, Cambridge, MA: MIT Press, 1996, pp. 533-609 for more information about spectrum analysis, including FFT.

⁵See Ibid. pp. 969-1016 for more information about MIDI

PV_MaxMagN⁶ phase vocoder unit generators. In order to have access to this data in the language side of SuperCollider, I used PV_MagBuffer and PV_FreqBuffer⁷ to store this information into a buffer. Once stored in a buffer, the information can be accessed as an array and be manipulated freely. Nevertheless, the buffer stores all of the bins of the FFT and therefore the bins with the magnitudes that were not empty have still to be collected and indexed to access the corresponding frequency values. The resulting arrays therefore only constitute the number of strongest bins, which can be defined by the user. Figure 4.1 shows an example of the frequency and magnitude arrays for the ten strongest bins. The purpose of this class is to have easy access to relevant FFT information

with the aim to convert frequencies and magnitudes either as MIDI messages or as data to be used to control synthesis definitions⁸. The incoming signal can be a live input in a performance situation, or a sound file. Lastly, this class also provides the feature of saving the spectral information triggered by an onset detector with the objective of creating a MIDI file by storing time values and converting the frequency and magnitude data to MIDI notes and velocities.

1.1.2 FFTFilter

FFTFilter inherits functionality from PartialTracker and uses the information of the frequency array to control the bandwidth and center frequency of a two pole resonant filter. This FFT controlled filter is designed to be used to filter a signal with a rich spectral content, such as different types of noise, with the information given by an FFT analysis of another signal that should be more limited

in its frequency range. A function is evaluated in a loop in which an argument that can be changed by the user represents the time value between each iteration. This function accesses the highest and lowest frequency values from the array calculated by the PartialTracker functionality every time the loop is evaluated. Since the purpose is to make a smooth line instead of discrete points, the signal must be lagged exponentially to produce a continuous control signal. By following this procedure, it is possible to approximately track the contour of the frequencies of a signal that have a stronger presence, given that the settings for the amount of strongest bins and magnitude threshold are appropriate for the specific spectral characteristics of the signal. Figure 4.2 shows a spectrogram of

Figure 1.2: FFTFilter: Spectral mapping of vocal contour.

speech and how the FFTFilter maps the contour of the vocal signal. Given that the vocal signal has a strong presence in a narrow frequency range, it is ideal to control the filter. FFTFilter therefore uses the continuous signal of the highest and lowest frequencies of the array to calculate the bandwidth and center frequency for the resonant filter. Figure 4.3 shows a visual representation of a fairly noisy signal that has been filtered by the resonant filter following the vocal contour as seen in Figure 4.2. Once the trajectory of the filter is set by the frequency data extracted from the FFT, an envelope follower maps the amplitude of the sound that was used as the FFT input to control the amplitude of the resonant filter. By combining the amplitude envelope and frequency contour of one sound to control a resonant filter that is applied to another sound, it is possible to incorporate characteristics of the analyzed sound to the filtered sound source.

Figure 1.3: FFTFilter: Noise filtered by vocal contour.

1.1.3 SpearToSC and SpearToMIDI

SpearToSC is a class that takes data from the open source software application called SPEAR⁹ and transfers it to an array in SuperCollider. SPEAR uses a variation of the traditional McAulay-Quartieri procedure and “attempts to represent a sound with many individual sinusoidal tracks (partials), each corresponding to a single sinusoidal wave with time varying frequency and amplitude.”¹⁰ SPEAR provides a graphical representation of a sound¹¹ (as seen in Figure 4.4) in which it is possible to select the individual sinusoidal tracks and allows to isolate and access the information for each individual partial. The amplitude and frequency information of each partial is given by frame can be stored in a text file. **SpearToSC** reads text files produced by SPEAR¹² as a string and strips it into a multidimensional array in SuperCollider. It is therefore possible to process this data within the SuperCollider language and server and re-synthesize this information not only with sinusoidal waves, but with any type of unit generator.

SpearToMIDI is a class that inherits functionality from **SpearToSC** and reduces the information given by SPEAR to be used as data to produce a MIDI file or to control SuperCollider synthesis definitions. The purpose of this class is to reduce the spectral information to an amount of data that can later produce notated material for a written score, a MIDI file or a control system to be used for triggering synthesis algorithms. The data in the text file generated by SPEAR is available by frame and gives too much information for this purpose. Therefore, **SpearToMIDI** reduces this data

in four stages: First, it takes an amplitude threshold argument which gets rid of all of the partial information that lies below this value (as seen in Figure 4.5). In other words, it breaks the partial

Figure 1.5: SpearToMIDI: Amplitude threshold selection.

in different groups by introducing silences instead of the data that lies below the threshold and at the same time keeps track of the beginning and the end of each group.

The second stage reduces data with a frequency modulation threshold. Each group is taken as a line and the computer only stores the points in the line which cross a given interval (the modulation threshold). For example, Figure 4.6 shows how the lines representing the groups in Figure 4.5 are traced by selecting the points that cross a given interval.¹³ If the interval is of one semitone then the

¹³The grid represents the intervals as shown in the y-axis. For the purpose of simplification, the diagram doesn't

Figure 1.6: SPEARToMIDI: Point selection through frequency modulation threshold.

frequencies are averaged to the closest chromatic note. It is possible to make microtonal divisions of the equal-tempered scale by using floating point values for the modulation threshold. The magnitude, frequency and time values for each point are stored as a collection of data. This collection can then be accessed and used to control synthesis definitions externally by generating envelopes, which gradually change frequency to produce glissandos and amplitude for gradual volume change. After these first two stages, the original data from Spear is reduced considerably by disregarding details that are not vital for the given purpose.

The third stage, takes the points of the lines that were obtained in the previous stage and translates them into single notes with a start and an end and that do not change in frequency and amplitude while playing— in other words, a format that is compatible with the MIDI note-on and note-off paradigm. The points are then considered as representing note-on messages and the note-off messages are calculated depending on whether the point is followed by another new point or if the point is the last of the group, in which case a silence would proceed. In other words, a note-off is inserted before a new note-on or just before a silence. Figure 4.7 shows the note representation derived from Figure 4.6, where the notes are seen as green lines, the note-on messages as blue points and the note off messages as green points. The results of this stage can be used to generate a MIDI file¹⁴ with the intention of either using it to trigger a sampler or to import it into a notation software to create a written score. The user can input the time signature and tempo for the MIDI file as well as an interval value that divides the MIDI note range into different MIDI tracks. By doing this, the notes are separated into different tracks depending on their value in relationship to each other

with the purpose of not having too many notes in the same track. Furthermore, these results can be used to create a list of OSC (Open Sound Control) commands that can be sent to the SuperCollider Server for Real-Time-Synthesis and Non-Real-Time-Synthesis. Extra arguments can also be added to control other values in the synthesis definition, which can be set individually by using a function to be evaluated for each instance of the definition.
